

Do network investment costs outweigh the benefits of integrating high shares of renewable generation into electricity networks?

1. Background

Ambitious **RES targets** require installing massive amounts of RES capacity over the next decade. Electricity grids are the backbone of the decarbonised, electrified society. Significant investment requirements of electricity grids are expected to integrate high RES shares.

2. Contributions

electricity •Analysis grid investment requirements of the for decarbonisation of the electricity sector, considering both transmission (T) and distribution (D) networks.

•Quantification of the cost of integrating high RES shares into large-scale

→ Goal: evaluate the impact of high RES shares on electricity grid reinforcement costs of large-scale electricity grids.

3. Scenario creation

Four 2030 scenarios are created for each zone to examine the impact of high RES deployment on grid costs. Generation (G&S) storage and requirements investment are combining determined by technology restrictions for additional G&S capacity and demand growth.

Scenario names combine G&S restrictions and demand growth.

Do not invest Invest cost-

Generation Demand profiles profiles & costs

Generation expansion model \rightarrow Installed capacity per technology \rightarrow Generation expansion costs

Geographical distribution of G&S Transmission expansion model

 \rightarrow System operating costs

- \rightarrow Transmission expansion costs
 - % of RES that is DG
 - Grid characterisation (urban, rural, etc.)

Distribution cost model \rightarrow Distribution expansion costs electricity grids. High RES scenarios are evaluated with a baseline without

additional renewable generation capacity (low RES).

5. Case studies

Consideration of three large-scale electricity grids representing different power systems selected based on their differences in:

 Availability of natural resources, load density, initial generation capacity mix and electricity grid (T&D) characteristics.

→ Central Illinois, Spain and Texas

Key parameters of the three selected electricity grids

	Central Illinois	Spain	Texas			
RES participation in the initial energy mix						
	13.5%	44.7%	12.3%			
Transmission (T) grid characteristics						
Number of nodes	200	479	2,000			
Length of lines (km)	2,585	36,273	48,580			
Peak demand (GW)	2.2	41	59			
Distribution (D) grid characterisation: share of RES to connect to D						
PV	60%	43%	25%			
Wind	0%	6%	0%			

0% demand growth0% & Low RES0% & High RES2.3% annual demand growth2.3% & Low RES2.3% & High RES		\rightarrow Low RES	\rightarrow High RES	
2.3% annual demand RES RES	0% demand growth	0% & Low RES	0% & High RES	
51000011	2.3% annual demand growth	2.3% & Low RES	2.3% & High RES	(in

Total system costs vestment + operation)

Results 6.

Despite increasing both G&S capacity and grid (T&D) investments, high RES scenarios reduce total annual system costs in all zones.

Annualised unit T&D grid costs for integrating RES capacity

7. Conclusions

Unit T&D grid investment costs represent 3 to 10% of the total investment costs in the high RES scenarios and 2 to 9% in the low RES scenario.

Required added G&S capacity increases significantly when moving from low

High RES scenarios allow for an average OPEX reduction of 51%, reducing total system costs (investment + operation) by 14%.

to high RES scenarios. However, injecting additional energy from RES leads

to 0.94 to 2.97 €/MWh incremental grid (T&D) investment.

 \rightarrow The saving potential of RES generation is in the operating cost reduction. Despite the increasing network investment costs, annualised system costs are reduced by around 6 to 18% compared to the corresponding low **RES** scenario.

 \rightarrow The power system has a low impact on the finding that investing in RES

allows for a decrease in system costs via the reduction of OPEX.
