Improving dairy production in central Nigeria

Most milk in central Nigeria is produced by cattle in low input, low yielding systems. Dairy productivity can be increased by using higher yielding breeds & feeding better quality diets.

This factsheet uses production systems from Kaduna Province as an example of how milk yields and income from dairy production can be improved in central Nigeria.

Current production systems

Most milk is produced for home consumption by indigenous cattle kept by pastoralists. Cattle are kept in large herds and graze on natural guinea savanna pasture managed in a traditional pastoral system by Fulani people. Crossbred dairy cattle are not common. Excess milk is sold at local markets.

Issues limiting milk production

Animal genetics
Local cattle breeds have low milk yields

Low quality feed
Cattle graze native perennial pastures without supplementation

High animal mortality & low reproduction rates
Largely caused by disease & poor nutrition

Modelled baseline household

- 62 Bunaji cattle (local breed)
- Cows graze guinea savanna pasture
- Calves weaned at 4 months and cows milked for up to 9 months

Modelled interventions to increase production

Improved pasture
Productivity and quality of pastures is improved through application of fertiliser and species composition. Herd size is increased to 107 head (local cattle).

Improved pasture + genetics
Local cattle replaced with Friesian-Bunaji crossbred dairy cattle (larger and higher yielding than local cattle). Higher pasture yields and quality can support 83 head.

Improved pasture + genetics + supplementation with concentrate
Local cattle replaced with Friesian-Bunaji crossbred dairy cattle. Cows supplemented 3 kg concentrate/cow.day. With additional supplementation, the improved pastures can support 94 head.

Using models to understand potential impacts

Bio-economic models can be used to simulate and understand the potential effects of changes to production systems. A baseline simulation is created to match current production systems, and different interventions are tested.

Models show what could happen, not what will happen, so results need to be interpreted with caution.

Key messages

Improved breeds such as Friesian cattle have higher genetic potential but are bigger and have higher nutrition and health care requirements compared to local cattle.

**Combined interventions are more successful than single interventions.**

The highest milk yields are achieved when higher yielding cattle breeds are fed high quality diets, particularly concentrate feeds.

Modelling of interventions shows the greatest increases in production come from combining multiple interventions.
